Introduction  The term pseudoaddiction was first used in 1989 to describe an iatrogenic syndrome resulting from poorly treated cancer pain. The index case was a 17 year old man with leukemia, pneumonia, and chest wall pain. The patient displayed behaviors (moaning, grimacing, increasing requests for analgesics) wrongly interpreted by the physicians and nurses as indicators of addiction, rather than of inadequately treated pain. The term pseudoaddiction is not a diagnosis, but rather a way to describe a phenomenon about the attitudes and motivation of clinicians in managing pain through our fears and mis-understanding of pain, pain treatment, and addiction.

Features
- Behaviors that suggest to the health care provider the possibility of psychological dependence (addiction):
  - Moaning or other physical behaviors in which the patient is trying to demonstrate to the provider that they are in pain.
  - Clock-watching or repeated requests for medication prior to the prescribed interval.
  - Pain complaints that seem “excessive” to the given pain stimulus.
- Inadequately prescribed and titrated opioids analgesics; typically the use of an opioid of inadequate potency and/or at an excessive dosing interval (e.g. oral morphine q6 hours PRN – see Fast Fact #18).

Assessment  Perform a complete pain and substance abuse assessment:
- Is this a pain syndrome that typically responds to opioids?
- Is the current opioid dose, route and schedule pharmacologically appropriate?
- Does the patient have a history of a substance abuse disorder? (FF #311-312)

Management  If you believe the current problem is under-treated pain leading to pain seeking behaviors (pseudoaddiction):
1) Establish trust. A primary issue in most cases is the loss of trust between the patient and the health care providers. The physician and nursing staff should meet to discuss how they will restore a trusting therapeutic relationship; outside assistance from a pain or palliative care service can be helpful. Plan to meet with the patient and openly discuss the events leading up to the current problem. Engage the patient in the decision-making process about the current and future use of analgesics.
2) Prescribe opioids at pharmacologically appropriate doses and schedules. Aggressively dose escalate until analgesia is achieved or toxicities develop (see Fast Facts #18, 20, 36). Frequently re-evaluate progress in pain management and ask for consultation assistance.
3) Pain behaviors due to pseudoaddiction can improve with the provision of adequate analgesia, including opioids. In contrast, behaviors associated with a substance abuse disorder will not change or worsen.
